Interproximal Reduction: A Twin Helix Device

Neeraj E Kolge, Vivek J Patni, Ravindranath VK, Divij Joshi, Amol Mhatre, Swapnagandha R Kate

ABSTRACT

Introduction: Interproximal enamel reduction dates back to 1944 when it was first advocated for correcting lack of tooth size harmony by stripping the proximal surfaces of the mandibular anterior segment. Despite convincing results, interproximal reduction (IPR) only became popular after the advent of bonding, as full-arch banding done previously completely deferred the use of this method for tooth material reduction. With the current status and ongoing development of new techniques of IPR, use of this method as a mean of gaining space has increased exponentially over the last three decades.

Procedure: A 12-inch length of 0.036” diameter wire is used for fabrication of the assembly. Helices of 2.5 mm diameter with two coils and the other according to finger grip are fabricated, and U-loops are prepared at the free ends for engaging the proximal strips. This assembly can be placed intraorally in the interdental region of our choice to cut the tooth material.

Conclusion: This assembly provides an effective grip rather than using hand held strips. It is also accessible in both anterior and posterior regions with a minimum requirement of armamentarium and can be sterilized and reused.

Keywords: Crowding, IPR, Slenderization, Twin Helix

INTRODUCTION

Various terms are used for the procedure of reduction of interproximal tooth material which in turn helps in attaining a good alignment and long-term stability of treatment goals. They are as follows:

• Interproximal enamel reduction
• Air-rotor stripping
• Slenderizing
• Reproximation

PROCEDURE

• A 12-inch length of 0.036” diameter wire is used for fabrication of the assembly.
• Bending of helices (Figs. 1A and B) is followed by 90° vertical bends are given on either side of the horizontal arm at the free ends of the wire (Fig. 2).
• U-loops are prepared at the free ends for engaging the proximal strips, and the excess wire is cut.
• 2.5 mm radius helix (with two coils) is made at one end of the wire while a helix with a diameter approximating the finger grip (Figs. 4 and 5) is made at the other end.
• Assembly (Fig. 6) can be placed intraorally in the interdental region of our choice to reduce the tooth material (Figs. 7A and B).

Advantages

• More effective than using loose hand-held strips.
• Accessibility in both anterior and posterior regions.

### REFERENCES

### CONCLUSION

Thus, this is an efficient, effective and economical tool for inter-proximal reduction.

- Minimum armamentarium required
- Can be sterilized and re-used
- Amount of proximal strip wastage is minimal
- Time-saving
- Economical
